HIV – What a paediatrician should know

HIV infection which was earlier a fatal disease in children is today a chronic disease which can be kept under control due to the availability of ART. However, still the incidence of childhood HIV infection is high, which is a cause for concern. The developed world has virtually eliminated the occurrence of this infection in children. This is mainly because of near elimination of mother to child transmission of this disease. In our country (developing world), majority of pregnant females do not have access to health care facilities, majority of those who have do not utilise these and many of those who in fact visit health care facilities do not get adequate counselling or measures to prevent MTCT of this infection.

Epidemiology

An estimated 2.5 million children worldwide are living with HIV/AIDS. About 10,000 become infected daily and 260,000 deaths of children below 15 occur due to AIDS related illnesses.

In US, the number of new children with AIDS/HIV infection increased from 1984 to 1992 and

infected daily and 260,000 deaths of children below 15 occur due to AIDS related illnesses.

In US, the number of new children with AIDS/HIV infection increased from 1984 to 1992 and then declined markedly by more than 95% to fewer than 100 cases per year. The estimated number of deaths occurring from AIDS-related illnesses are fewer than estimated five years back. This is probably due to increased access to treatment and reduced MTCT. The United Nations General Assembly is committed to 'accelerate progress towards the elimination of new child infections by 2015, reducing the number of new HIV infections among children by
